

Restaurant POS – Offline-First Architecture

Next.js static export (no server) · SQLite as source of truth · Supabase Realtime used only as a relay for kitchen order events. Packaged via Capacitor (APK) and Tauri (EXE) from the same codebase.

- Offline path – always works, no internet required
- Online path – only used to push order to kitchen display
- Packaging shell

What's offline: order taking, bill generation, KOT generation, local printing, local reporting, menu management. None of this ever waits on a network call.

What's online: exactly one thing – pushing the KOT ticket to the kitchen display in real time. If that fails, the printed KOT already covers the kitchen.

Sync queue behavior: every KOT insert also writes a row to a local outbox table. A background watcher checks connectivity and drains the outbox to Supabase, retrying with backoff on failure.

Why not Next.js API routes: APK/EXE builds have no Node server at runtime – routes would 404. Supabase client calls happen directly from the browser bundle instead.
